# 3VA Selectivity Tables

## Introduction

Different global markets (UL, IEC, etc.) evaluate the selectivity, or coordination, of overcurrent protection devices in different ways. In the IEC world, selectivity tables are common, and these are usually based on a comparison of the let-through energy of the downstream device and the amount of energy required by the upstream device to operate. In the North American market (UL) the accepted convention has been to plot the published time current characteristic curves (TCC) of two devices and evaluate the spacing between the two curves. NFPA 70, the National Electrical Code®, defines required levels of coordination for two specific applications: 1) Article 517 Health Care Facilities; and 2) emergency or standby systems in Articles 700, 701 and 708. In the first, the required coordination would be demonstrated by a plot showing no overlap between two curves (including tolerances) down to a time of 0.1s. In the second, the required coordination, defined as Selective Coordination, must demonstrate no overlap in the plotted curves, by convention to a level of 0.01s (the minimum generally published values). In both cases evaluation of the curves only occurs up to the level of the calculated available fault current at the downstream device – overlap above that value is disregarded since there isn't enough current to operate in that region.

In applications not covered by Articles 517, 700, 701 and 708, the historical convention for the demonstration of coordination has been to make sure there was adequate space (usually defined at the discretion of the Engineer-of-Record) between the plots in the thermal region. Evaluation of the

instantaneous region usually depends on whether the devices are low voltage power circuit breakers (instantaneous coordination can be adequately programmed because the trip unit determines when the contacts open) or molded case circuit breakers, either thermal magnetic or ETU (the contacts open by magnetic repulsion at the onset of a large overcurrent regardless of the commands from the trip unit). In the latter condition coordination will be dependent on a number of factors including the actual current flowing during a fault (limited by the combined arc impedances of all molded case breakers in the path) and the relative size of the breakers (in general, smaller frame breakers clear faults more quickly than larger frame breakers, sometimes resulting in inherent coordination). Presently available power study software do not include these last two important points in the fault current computation or plotting because these phenomena are not empirically calculable due to the lack or variability of data.

### The EasyTCC Application

Siemens publishes the TCC's for all its circuit breakers, and these are then used by various power study software providers. Siemens has a free application, EasyTCC®, which allows comparative plotting of all Siemens TCC's. *The purpose of this document is to provide a quick and easy method to identify if, and to what value, the TCC plots for two Siemens circuit breakers overlap when plotted using the EasyTCC application. The data is based on the actual plot output of EasyTCC and should be duplicable in any similar platform that uses the same published curves.*

# How to interpret curves in the **EasyTCC** application

## Example Curve 1

The **green** line shows the border of coordination to 0.1s (NEC 517), the **red** line shows the border of Selective Coordination (from a practical standpoint because most TCCs only show down to 0.01s and values below that point may not be valid depending on the actual closing angle of the fault), and the **blue** line shows the available fault current. To be interpreted as coordinating to 0.1s there can be no overlap in **Area A**. To be interpreted as Selective Coordination there can be no overlap in both **Area A** and **Area B**. **Area C**, because there is not enough fault current to operate in that area, is disregarded.

## Example Curve 2

In the example above both coordination to 0.1s **and** Selective Coordination are demonstrated because there is no overlap up to the available fault current. In the tables that follow, when a numeric value is shown in a cell (not Y or N), it represents the lowest available fault current in amperes that still demonstrates Selective Coordination (in this case 2kA).

**Example Curve 3**

These curves **do not** demonstrate coordination to 0.1s **or** Selective Coordination because of the overlap above 0.1s. These breakers would be shown as **N** in the tables.

**Example Curve 4**

These curves **do** demonstrate coordination to 0.1s **but not** Selective Coordination. These breakers would show a value of 2kA in the tables because they demonstrate both coordination to 0.1s and Selective Coordination to the left of an available fault current equal to that value. Coordination to 0.1s in the vast majority of conditions indicates selectivity in the full thermal range. If NEC sections 517, 700, 701 or 708 do not apply, the Engineer-of-Record can use this information to determine coordination.

### Example Curve 5

These curves demonstrate both coordination to 0.1s and Selective Coordination at any available fault current because they show no overlap at any value. These breakers would be shown as **Y** in the tables.

## 3VA Selectivity Tables **Sorted** by **Downstream** breaker

**IMPORTANT:** It is assumed that any adjustable trip function is set to the highest possible setting. Any trip unit that is set at a lower setting will need to be individually evaluated for selectivity.

How to read the following tables:

The plots of the two breakers show overlap above 0.1s and are generally not considered to be coordinated. In cases of especially low available fault currents, the Engineer-of-Record may plot these two breakers to see if they demonstrate coordination in the thermal region up to the available fault current (Note, however, that in this condition there isn't enough current to trip in the instantaneous region so arc flash hazard may be increased due to the extended clearing time)

**3VA51, to 125A Upstream**

| Downstream 3VA41 | Amps | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50  | 60  | 70  | 80  | 90   | 100  | 110  | 125  |

The plot of the two breakers shows no overlap at currents less than or equal to the value shown (830A in this example), so they may be considered as showing both coordination to 0.1s and "Selective Coordination" to that level.

The plots of the two breakers do not overlap at any available fault current so are considered to both coordinate to 0.1s and to demonstrate "Selective Coordination".

**NOTE:** Not all possible downstream breakers are shown. It can, however, be said that in the case of three breakers, A upstream, B one tier downstream, and C two tiers downstream, if B and C show "Y" relative to each other, A and C are to be considered coordinated to the same degree as A and B.

**Table 1 3VA41, to 125A Upstream**

| Downstream 3VA41 | Amps | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50  | 60  | 70  | 80  | 90  | 100 | 110 | 125  |
